

Homework Problem Set 7: Margins of Error and Confidence Intervals for Estimating μ and p

Answers are given at the end.

Use statdistributions.com to look up values of z and t to use for computing margins of error and confidence intervals. Use the standard normal distribution to look up z and use Student's t distribution to look up t .

Mendel's Peas

In an earlier practice problem you encountered a classic study by Gregor Mendel on the inheritance of the trait of color in pea plants. He bred pea plants by crossing plants from a strain that only produced green peas with another strain that only produced yellow peas. The first-generation offspring from this crossbreeding then produced a strain of pea plants that were presumed to carry the genes for both yellow and green peas — one from each parent. However these plants only had yellow seeds because it was assumed that the yellow genes are dominant in the sense that an offspring with at least one gene for yellow peas will always have yellow peas. The only way for a plant to have green peas is if both genes were for green peas. The plants from the first-generation offspring were then crossed with themselves to produce the second-generation offspring.

What was particularly relevant to Mendel was the *probability* that a second-generation offspring would have yellow peas because this probability has implications for Mendel's ideas about genetics and inheritance. Let p represent this probability. In one study Mendel produced 8023 second-generation offspring, so we have 8023 observations of the variable color (i.e., yellow or green), and for 6022 of the 8023 observations the color was yellow. Use this information to compute the *margin of error* for estimating p , as well as the *confidence interval* to estimate p . Use a confidence level of 95%.

The Trebuchet at Château des Baux

Several years ago I saw a working full scale working trebuchet at Château des Baux in Les Baux-de-Provence. Suppose that engineers want to know the mean distance this trebuchet will throw a projectile of a given weight. Let x be the distance that the trebuchet throws a projectile on a given observation. This is a random variable from our perspective because various uncontrollable factors will cause x to vary from observation to observation. The engineers want to know is μ , the mean distance that the trebuchet throws a projectile. To estimate μ they fire the trebuchet 25 times to produce 25 observations of x . From this sample they compute a mean distance of 250 meters and a standard deviation of the distances of 15 meters. Compute the *margin of error* for estimating μ , and the *confidence interval* to estimate μ . Use a confidence level of 95%.

Experiments for Extra Sensory Perception

Some early experiments designed to test for extra sensory perception (ESP) used “Zener cards” named after Karl Zener.¹ A typical pack of cards contains 25 cards that are each printed with one of five symbols. Each symbol appears in the deck five times. Examples of each card are shown in Figure 2.

¹See en.wikipedia.org/wiki/Zener_cards.

In a typical experiment, the deck would first be shuffled and then the experimenter would select a card from the deck, study it, but not show it to the subject. The subject would then be asked “read the mind” of the experimenter to determine the symbol on the card. This would proceed until all of the cards in the deck had been exhausted, although it could be repeated as many times as desired by reshuffling the deck and going through it again. The subject would not be told if they were correct or incorrect so they could not more easily guess later cards by simply determining which cards had already been seen.

The table below shows the results from testing four subjects with Zener cards. Each row shows the name of the subject, the number of times they correctly read/guessed the card, and the number of times they went through the deck of 25 cards.

Hobbit	Correct	Cards
Frodo	4	25
Merry	12	50
Pippin	39	75
Sam	26	100

So, for example, out of 50 cards (i.e., two decks), Merry read/guessed the correct card 12 times (note that the sample size is the number of *cards*, not the number of decks). For each subject we can imagine a population distribution of the following form.

x	$P(x)$
correct	p
incorrect	$1 - p$

That is, for a randomly selected card they will correctly read/guess the card with probability p , and be incorrect with probability $1 - p$. It is of interest to estimate p , because if we can clearly show that p is larger than 0.2 (which is the probability of being correct *by guessing*) then that would be interpreted as evidence that the subject has some capacity for ESP (albeit not perfect unless $p = 1$). Let p_f , p_m , p_p , and p_s denote the probability of correctly reading/guessing a card for each of the four subjects (the subscripts correspond to the first letter of their names). For each parameter, use the information given above to provide a point estimate, the standard error, the margin of error, and a confidence interval for the probability that they can correctly read/guess the card. Use a confidence level of 95%.

Survey of Daphnia Density

Daphnia are a genus of tiny planktonic crustaceans found in freshwater lakes, ponds, streams, and rivers. In addition to being an organism of interest to biologists, ecologists, and fisheries researchers, the health of daphnia are often used to help assess the general health of a freshwater ecological system. A survey obtained several one-liter samples of water from a lake at different depths.² The depths corresponded to three layers of

[illegible]

Layer	\bar{x}	s	n
epilimnion	19.50	3.58	20
thermocline	11.30	4.08	10
hypolimnion	1.73	1.91	15

Layer	\bar{x}	s	n
epilimnion	19.50	3.58	20
thermocline	11.30	4.08	10
hypolimnion	1.73	1.91	15

3

Mendel's Peas (Solutions)

Rounding to the fourth decimal place, the margin of error is approximately 0.0095 and the confidence interval is approximately 0.7506 ± 0.0095 or (0.7411, 0.7601). Note that the margin of error is relatively small because the sample size is relatively large.

The Trebuchet at Château des Baux (Solutions)

The margin of error is 6.192 meters, and the confidence interval is 250 ± 6.192 meters or (243.808 m, 256.192 m).

Experiments for Extra Sensory Perception (Solutions)

The table below gives the point estimate, standard error, margin of error, and confidence interval for p_f , p_m , p_p , and p_s .

Hobbit	Point Estimate	Standard Error	Margin of Error	Confidence Interval
Frodo	0.16	0.073	0.144	(0.016, 0.304)
Merry	0.24	0.060	0.118	(0.122, 0.358)
Pippin	0.52	0.058	0.113	(0.407, 0.633)
Sam	0.26	0.044	0.086	(0.174, 0.346)

Note that the results shown above were rounded, but no rounding was performed in intermediate calculations. Your answers may differ slightly.

If someone can only guess the correct card, the probability that they would be correct is $p = 0.2$. Note that every confidence interval *except* that for Pippin contains $p = 0.2$. Perhaps he has ESP?

Survey of Daphnia Density (Solutions)

The table below gives the point estimate, standard error, margin of error, and confidence interval for each layer of μ_e , μ_t , and μ_h .

Layer	Point Estimate	Standard Error	Margin of Error	Confidence Interval
epilimnion	19.50	0.80	1.68	(17.82, 21.18)
thermocline	11.30	1.29	2.92	(8.38, 14.22)
hypolimnion	1.73	0.49	1.06	(0.67, 2.79)

Note that the results shown were rounded, but no rounding was performed in intermediate calculations. Your answers may differ slightly. The table below shows the standard error, margin of error, median error, and mean error for each layer.

Layer	Standard Error	Margin of Error	Median Error	Mean Error
epilimnion	0.80	1.68	0.54	0.64
thermocline	1.29	2.92	0.87	1.03
hypolimnion	0.49	1.06	0.33	0.39

Note that the results have been rounded.
